TRANSMITTAL LETTER

Transmitted herewith for filing in the above-identified case are the following documents:

- ☒ Twenty-nine (29) pages of Specification, including twenty (20) claims and one (1) Abstract page;
- ☒ Thirteen (13) sheets of *Informal* drawings (Figs. 1-13);
- ☒ Twenty-one (21) pages representing Appendix I;
- ☒ Combined Declaration and Power of Attorney;
- ☒ Verified Statement Claiming Small Entity Status (37 C.F.R. 1.9(f) & 1.27(c);
- ☒ Assignment Recordation Coversheet *with* Original Assignment;
- ☒ Check in the amount of \$345.00 to cover the Application Filing fee;
- ☒ Check in the amount of \$40.00 to cover the Assignment Recordation fee; and
- ☒ Return-receipt postcard.

The Commissioner is hereby authorized to charge any deficiency or credit any overpayment required under 37 CFR §§ 1.16 – 1.17 to Deposit Account No. 01-2511. A duplicate copy of this transmittal is enclosed for this purpose.

Respectfully submitted,

Date:

ATTORNEY FOR APPLICANTS

**VERIFIED STATEMENT CLAIMING SMALL ENTITY STATUS**  
**(37 CFR 1.9(f) & 1.27(c)) - SMALL BUSINESS CONCERN**

Applicant or Patentee: Amanat, I., and Bundy, M.,  
Serial or Patent No.: Unassigned  
Filed or Issued: Filed Herewith  
Title: Apparatus and Method for Load Balancing Among Data Communications  
Ports In Automated Securities Trading Systems

I hereby declare that I am

- ☐ the owner of the small business concern identified below;  
☒ an official of the small business concern empowered to act on behalf of the concern identified below.

NAME OF SMALL BUSINESS CONCERN TRADESCAPE TECHNOLOGIES, L.L.C.  
ADDRESS OF SMALL BUSINESS CONCERN 499 Park Avenue, Suite 22  
New York, New York 10022

I hereby declare that the above identified small business concern qualifies as a small business concern as defined in 13 CFR 121.12, and reproduced in 37 CFR 1.9(d), for purposes of paying reduced fees to the United States Patent and Trademark Office, in that the number of employees of the concern, including those of its affiliates, does not exceed 500 persons. For purposes of this statement, (1) the number of employees of the business concern is the average over the previous fiscal year of the concern of the persons employed on a full-time, part-time or temporary basis during each of the pay periods of the fiscal year, and (2) concerns are affiliates of each other when either, directly or indirectly, one concern controls or has the power to control the other, or a third party or parties controls or has the power to control both.

I hereby declare that rights under contract or law have been conveyed to and remain with the small business concern identified above with regard to the invention described in the document identified above entitled:

Apparatus and Method for Load Balancing Among Data Communications Ports In Automated Securities Trading Systems  
(Title of the Invention)

If the rights held by the above identified small business concern are not exclusive, each individual, concern or organization having rights in the invention must file separate verified statements averring to their status as small entities, and no rights to the invention are held by any person, other than the inventor, who would not qualify as an independent inventor under 37 CFR 1.9(c) if that person made the invention, or by any concern which would not qualify as a small business concern under 37 CFR 1.9(d), or a nonprofit organization under 37 CFR 1.9(e).

Each person, concern or organization having any rights in the invention is listed below:

- ☒ no such person, concern, or organization exists.  
☐ each such person, concern or organization is listed below.

I acknowledge the duty to file, in this application or patent, notification of any change in status resulting in loss of entitlement to small entity status prior to paying, or at the time of paying, the earliest of the issue fee or any maintenance fee due after the date on which status as a small entity is no longer appropriate. (37 CFR 1.28(b))

I hereby declare that all statements made herein of my own knowledge are true and that all statements made on information and belief are believed to be true; and further that these statements were made with the knowledge that willful false statements and the like so made are punishable by fine or imprisonment, or both, under section 1001 of Title 18 of the United States Code, and that such willful false statements may jeopardize the validity of the application, any patent issuing thereon, or any patent to which this verified statement is directed. I hereby declare under penalty of perjury under the laws of the United States of America that the foregoing is true and correct.

NAME OF PERSON SIGNING SEEMA KHAN  
TITLE OF PERSON IF OTHER THAN OWNER General Counsel

APPLICATION FOR PATENT

TITLE: APPARATUS AND METHOD FOR LOAD BALANCING  
AMONG DATA COMMUNICATIONS PORTS IN  
5 AUTOMATED SECURITIES TRADING SYSTEMS

INVENTORS: IRFAN AMANAT  
MICHAEL BUNDY

10 ATTORNEY DOCKET NUMBER: 30411US

SPECIFICATION

15 BACKGROUND

Broker-dealer systems for automated trading of securities need to be fast. Broker-dealer systems receive orders from customers, send the orders to markets, receive responses from markets, and communicate order status to customers. Orders are sent to markets  
20 through data communications ports. Responses are received from markets through data communications ports. Ports are dedicated to particular markets. Data communications ports have limitations upon the number of orders that can be sent through them in a particular period of time or the number of orders without acknowledgments that can be sent through them. If more orders arrive than can be sent through a port in a particular  
25 period of time, the broker-dealer system is slowed. If a port partially fails or is slowed for mechanical or electrical reasons, the broker-dealer system is slowed. If a port fails completely, the broker-dealer system is disabled with regard to the market served by that port.

Broker-dealers often add additional ports to their systems, so that more than one port is dedicated to a particular market. Adding ports improves overall throughput of orders to markets and reduces the risk of being completely disabled with respect to a market if a port fails. System performance can still vary widely, however, from the point of view of a customer whose order is sent through a port that is slowed or stopped by overload or mechanical failure. Such a customer experiences the harmful effect of a lack of balance in the communications load among the ports for the market to which the customer's order was intended. Methods and systems are needed for balancing the communications loads among ports for markets in support of the overall quality of data communications in broker-dealer systems.

## SUMMARY

A first aspect of the invention provides methods of balancing data communications loads among data communications ports in systems for automated trading of securities. The systems for trading securities include at least one broker-dealer system coupled through at least one data communications system to more than one market system. Data communications systems include ports organized so that one market is coupled to the broker-dealer system through more than one port. Embodiments of the invention include methods of load balancing applied when a new order from the broker-dealer system is available and ready to be sent through a port to a market. The inventive methods in typical embodiments are applied continually in turn to each port assigned to a market.

Embodiments of load balancing methods typically include the steps of receiving acknowledgments of orders previously sent through a port from a broker-dealer system to a market, sending acknowledgments to the broker-dealer system, and determining that port are not overloaded. Various embodiments of the present invention make determinations of overload on the basis of latency, net order count, or order count

compared with acknowledgment count.

Alternative embodiments of the invention send orders only through least-loaded ports. Least-loaded ports are identified on the basis of latency, net order count, or a combination  
5 of the two.

A second aspect of the invention provides a load balancing system for automated trading of securities in which data communications loads are balanced among data communications ports. Embodiments of a load balancing system are typically coupled to  
10 a multiplicity of ports organized so that one market is coupled to a broker-dealer system through more than one port. Embodiments of a load balancing system typically function when a new order from a broker-dealer system is available and ready to be sent through a port to a market. Embodiments of a load balancing system are typically operative continually in turn upon each of the ports assigned to a market.

Embodiments of the load balancing system typically comprise at least one computer processor coupled for data communications to at least one broker-dealer system and coupled through data communications ports to more than one market. In typical  
15 embodiments, the processor is programmed to receive through a port from a market to which the port is coupled a new acknowledgment of an order previously sent through the port from the broker-dealer system to the market. The processor in typical embodiments  
20 is programmed to send the new acknowledgment to the broker-dealer system.

The processor in typical embodiments of this second aspect of the invention is  
25 programmed also to determine that the port is not overloaded, with overload being determined according to measures of latency, net order count, or order count and acknowledgment count. The processor in most embodiments is programmed also to send a new order through the port to the market. Many embodiments of the load balancing system include computer memory coupled to the processor with the processor

programmed also to store in computer memory the new acknowledgment and the new order.

In many embodiments of the invention, the processor is programmed also to send orders to markets only through least-loaded ports. Processors are typically programmed to determine that a port is least loaded dependent upon latency, net order count, or a combination of latency and net order count.

## DETAILED DESCRIPTION OF EXEMPLARY EMBODIMENTS

### Definitions:

“Acknowledgment” is a response from a market in which an order has been placed, the  
10 response being a confirmation that an order has been received by the market.

“Coupled,” except when context requires otherwise, means coupled for data  
communications. This is particularly the case when describing broker-dealer systems as  
being coupled to markets through data communications ports. Broker-dealer systems  
15 typically are coupled to ports, which ports in turn typically are coupled to markets.  
Methods of coupling for data communications useful with the invention include all forms  
of data communications networks, intranets, extranets, internets, local area networks,  
wide area networks, dedicated lines, satellite links, and the like. Any functional method  
of data communications is well within the scope of the invention.

20

“ECN” abbreviates “Electronic Communications Network,” referring to an order  
matching service that provides liquidity by matching orders rather than by maintaining  
inventory. In the context of the invention, ECNs are considered markets. ECNs, like  
market makers are identified by use of market participant identification codes or  
25 “MPIDs.” In order to avoid confusion with data communications networks, ECNs are  
referred to as either “ECNs” or as “markets.” Some current ECNs, their symbols and  
names, are listed below. The number and identities of ECNs changes from time to time.

**Example List of ECNs**

<b><u>MPID</u></b>	<b><u>Name</u></b>
ARCA	Archipelago
BTRD	Bloomberg Trade Book
INCA	Instinet
ISLD	Island
MWSE	Midwest Stock Exchange
NTRD	NexTrade
REDI	Speer Leeds

“Exchange” means a national, regional, or international exchange for securities trading including for example, Nasdaq or NYSE.

- 5 “Execution,” is a kinds of response to an order from a market, the execution indicating that the order has been at least partly filled, that is, that shares have been either bought or sold according to the side of the order.

- 10 “Filled” means executed. That is, all shares in the order have been executed, bought or sold according to the side of the order. If an order is subject to partial fulfillment, then the order can be partly filled and partly rejected or cancelled, in which case the order will never be considered filled. Processing of an order can therefore be completed through some combination of cancellation, rejection, killing, and partial execution without the order’s ever being filled. Processing of an order is said to be complete when all the
- 15 shares in the order, share by share, have been executed, cancelled, rejected, or killed.

“Latency” means a measure of the speed with which markets respond to orders and cancellations. Latency in many embodiments of the invention is determined as the difference between the time when a response to an order is received and the time when the corresponding order was routed to the market. Latency can be measured from normal orders or from test orders. Some markets support test orders as such. For markets in which test orders as such are not supported, test orders can be implemented by use of unmarketable orders immediately followed by cancellations. For markets receiving orders regularly, latency can be tracked from normal orders, without the need for test orders. Latency can be embodied as a single ratio difference between two recorded times or as various kinds of averages. One type of average latency useful with the invention is a moving average latency, a latency in which the average is dependent upon a number of recorded times for orders and acknowledgments, the times being recorded during a defined period of time, such as, for example, one trading day. Another type of average latency useful with the invention is a decaying average latency, in which the average is dependent upon a set number N of recorded times for orders and acknowledgments, the set number defining the N most recently recorded times. Other kinds of average latencies can be used, all of them being well within the scope of the invention.

“Level Two Quotes” are quotes that comprise one or more market participant quotes (“MPQs”). The best known source of level two quotes is Nasdaq, but “level two quotes” refers to any form of market information that aggregates market participant quotes for a security.

“Market,” “electronic market,” “market participant,” “electronic market participant,” “marketing network,” “electronic communications network,” “ECN,” “exchanges,” and “electronic marketing network” are all used as synonyms for services accessible through electronic communications networks capable of executing orders for securities by accepting from broker-dealers buy orders and sell orders, matching or failing to match

buy orders with sell orders, and communicating the results to the broker-dealers. Generally the term “market” is used to refer to these entities.

5 “Market maker” means a broker-dealer providing order matching and liquidity in a stock by maintaining an inventory of the stock. Market makers typically trade their inventories through exchanges. Some currently active market makers, their symbols and names, are listed below. The number and identity of market makers can change from time to time.

**Example List of Market Makers**

<b><u>MPID</u></b>	<b><u>Name</u></b>
BEST	Bear, Stearns & Co., Inc.
BTAB	Alex, Brown & Sons, Inc.
GSCO	Goldman, Sachs & Co.
HMQT	Hambrecht & Quist, LLC
HRZG	Herzog, Heine, Geduld, Inc.
JANY	Janney Montgomery Scott, Inc.
LEHM	Lehman Brothers, Inc.
MADF	Bernard L. Madoff
MLCO	Merrill Lynch, Pierce, Fenner & Smith Inc.
MOKE	Morgan, Keehan & Co., Inc.
MONT	Nationsbanc Montgomery Securities, LLC
MSCO	Morgan Stanley & Co., Inc.

NITE	Knight Securities, L.P.
OLDE	Olde Discount Corporation
OPCO	CIBC Oppenheimer Corporation
PIPR	Piper Jaffray Inc.
PRUS	Prudential Securities, Inc.
PWJC	Paine Webber, Inc.
RAJA	Raymond James & Associates, Inc.
SBSH	Smith Barney, Inc.
SHRP	Sharpe Capital, Inc.
SHWD	Sherwood Securities Corporation

“Orders” are orders for purchase or sale of securities. In the embodiments described, “orders” are electronic orders for purchase or sale of securities.

5 “Quotes” are aggregates of information regarding securities traded in markets. Quotes include for securities listed for sale or purchase, symbols identifying the securities, price, side, quantities, and market identifications or MPIDs. Quotes can come from exchanges or directly from markets. A “Nasdaq Level Two Quote” includes market information in the form of market participant quotes for all markets offering to buy or sell a particular  
10 security through Nasdaq.

“Securities” are any agreement for investment. Stocks are the securities most often addressed in described embodiments of the invention. The invention, however, is applicable to many kinds of securities including, for example, options, commodities, and  
15 bonds.

“Side” refers to which side of the market is represented by an order or a quote. Side indicates whether the quote or order is to buy or sell, bid or ask. “Bid” indicates the buy side. “Ask” indicates the sell side. The present invention functions equally for either

side of a transaction. Therefore we attempt to speak in neutral terms regarding side. We speak of execution rather than buying or selling. We use the term “price improvement” to indicate both price reductions for buy orders and price increases for sell orders.

5

#### Detailed Description:

Figure 1 shows an overview of a first aspect of the invention, a method (102) of load balancing data communications ports in systems for automated trading of securities.

10 In the first illustrated embodiment, the systems include at least one broker-dealer system (106) coupled for data communications (140) through at least one data communications system (104) to more than one market (130-134). The illustrated embodiment of the data communications system is coupled to a multiplicity of data communications ports (110-126) organized so that one market (130) is coupled to the broker-dealer system through  
15 more than one port (110,112). The method (102) is applied when a new order (108) from the broker-dealer system (106) is available and ready to be sent through a port to a market. In typical embodiments, the method is applied continually in turn to each of the ports assigned to a market.

20 Figure 2 is a more specific illustration of certain embodiments of the invention. One embodiment shown in Figure 2 includes receiving (202) through a port (218) from a market (222) to which the port is coupled (252) a new acknowledgment (204) of an order (230) previously sent through the port from the broker-dealer system to the market. This embodiment includes sending (206) the new acknowledgment (204) to the broker-dealer  
25 system (106) where the new acknowledgment is stored in computer memory (226) with other acknowledgment (224). The illustrated embodiment includes determining (208) that the port is not overloaded, the determination being dependent upon the previously-sent order (230), the new acknowledgment (204), and optionally also dependent upon other previous orders (228) and upon previous acknowledgments (224). The illustrated

embodiment also includes sending (210) a new order (212) through the port to the market. Sending (210) the new order is dependent upon the determination (208) that the port is not overloaded. That is, in this embodiment, new orders are sent to markets only through ports that are not overloaded.

5

In a further embodiment shown in Figure 3, determining (208) that the port is not overloaded further comprises determining (326) that a latency (320, 322) for the port is less than a maximum allowed latency (324) for the port. Latency comprises a measure of the speed with which markets return acknowledgments for orders.

10

As shown in Figure 3, in one embodiment, the latency for the port is an instant latency (320). In an alternative embodiment, the latency for the port is an average latency (322). In embodiments using latencies as shown in Figure 3, the port latencies are dependent upon orders (310) and acknowledgments (312) in that the latencies comprise various kinds of comparisons between order times (314), the times when particular order were sent to a market, and acknowledgment times (316), the times when acknowledgments corresponding to particular orders were received back from markets.

15

20

More specifically, an instant latency (320) is the difference between the time when a recent acknowledgment was received and the time when the acknowledgment's corresponding order was sent. In addition, as shown in Figure 5, an average latency in some embodiments is a decaying average (524) and in other embodiments is a moving average (522). Examples of methods and systems useful with the present invention for calculating latencies are set forth in Appendix I. The use of any method of calculating latency is well within the present invention.

25

A further embodiment shown in Figure 4 includes decrementing (402) a net order count (504) for the port (218), wherein the net order count (504) indicates the net number of orders sent through the port to the market for which acknowledgments have not yet been

received from the market. The net order count (504) for the port (218) is stored in computer memory in a port data structure (502).

An example of a port data structure useful in many embodiments of the invention is shown in Figure 5. The term “port data structure” means a data structure for storing data descriptive of the port. It does not mean that the port data structure is part of the port. On the contrary, in most embodiment, port data structures are stored in computer memory in a communications system in which a method of load balancing method is implemented according to the present invention.

The further embodiment illustrated in Figure 4 includes determining (404) that the net order count (504) is less than a maximum allowed net order count (506) for the port. The maximum net order count (506) indicates the maximum number of orders without acknowledgments allowed to be sent through the port (218). The fact that the net order count (504) is less than the maximum net order count (506) for the port (218) indicates that the port (218) is not overloaded.

This further embodiment shown in Figure 4 includes incrementing (406) the net order count. Alternative embodiments increment (406) the net order count (504) after determining (404) that the net order count (504) is less than the maximum net order count (506) for the port but before (408) sending (210) a new order (212) to market (222). Other embodiments increment (406) the net order count (504) after determining (404) that the net order count (504) is less than the maximum net order count (506) for the port (218) and also after (410) sending (210) a new order (212) to market (222).

A further embodiment shown in Figure 6 includes incrementing (602) an acknowledgment count (510) for the port (218). The acknowledgment count (510) represents the number of acknowledgments received through the port (218) during a defined period of time. An example of a period of time useful with various embodiments

of the invention is one trading day. Other embodiments use other time periods, some shorter, some longer. Any functional time period is within the scope of the invention.

A further embodiment shown in Figure 6 includes determining (604) that an order count (508) for the port (218) exceeds the acknowledgment count (510) for the port (218) by at least a maximum net order count (506). The order count (508) represents the number of orders sent through the port (218) during the defined period of time. The maximum net order count (506) indicates the maximum number of orders for which acknowledgments have not been received allowed to be sent through the port. The fact that the order count (508) for the port (218) exceeds the acknowledgment count (510) by at least the value of the maximum net order count (506) indicates that the port (218) is not overloaded.

This illustrated embodiment of Figure 6 includes incrementing (606) the order count for the port. Alternative embodiments increment (606) the order count (508) after determining (604) that the order count (508) for the port (218) exceeds the acknowledgment count (510) by at least the value of the maximum net order count (506) but before (608) sending (210) a new order (212) to market (222). Other embodiments increment (606) the order count (508) after determining (604) that the order count (508) for the port (218) exceeds the acknowledgment count (510) by at least the value of the maximum net order count (506) and also after (610) sending (210) a new order (212) to market (222).

A further embodiment of the invention as shown in Figure 7 includes determining (740), before sending (206) the new order (212) through the port (216) to the market (222), that the port is a least-loaded port. In this kind of embodiment, sending (206) the new order (212) through the port to the market is dependent (750) upon determining that the port is a least-loaded port (740).

More specifically, in this kind of embodiment, shown in Figure 7, utilizing detection of

least-loaded ports for load balancing, new orders typically are sent only through ports determined to be least-loaded. "Least-loaded" means generally that according to some measure of data communications load, the load of the subject port is at least as low as any other port. That is, although there may be other ports for the market having the same  
5 load as the subject port, there is no port with a lower load. Measures of data communications load useful with the invention include, for example, measure of latency and net order count.

In a specific embodiment shown in Figure 7, determining that the port is a least-loaded  
10 port (740) further comprises determining (742) that the net order count (710) for the port (216) is not greater than any of the net order counts (720, 730) for the other ports (218, 220) coupled to the market (222). In this illustrated embodiment, determining (742) that the net order count (710) for the port (216) is not greater than any of the net order counts (720, 730) for the other ports (218, 220) coupled to the market (222) is the indication that  
15 the port (216) is a least-loaded port. As shown in Figure 7, the embodiment provides data structures (702, 704, 706) for computer memory in which are stored the net order counts (710, 720, 730), one data structure (702, 704, 706) corresponding (703, 705, 707) to each port (216, 218, 220). The net order counts (710, 720, 730) indicate the net number of orders sent through the ports (216, 218, 220) to the market (222) for which  
20 acknowledgments have not yet been received from the market.

An alternative embodiment shown also in Figure 7 determines (740) the port (216) to be least-loaded by determining (744) that a latency (712) for the port is not greater than any of the latencies (722, 732) for the other ports (218, 220) coupled to the same market  
25 (222). In this illustrated embodiment, the latencies (712, 722, 732) are stored in port data structures (702, 704, 706), one data structure for each port. Latency comprises a measure of the speed with which markets return acknowledgments for orders.

Each port, in the illustrated embodiment of Figure 7, is characterized by a measured or

calculated latency( 712, 722, 732). The latencies in various embodiments are instant latencies, moving average latencies, decaying average latencies, or other forms of latency. Most forms of measurement or calculation of the speed or time delay required to send orders to a market through a port and receive in return corresponding  
5 acknowledgments are functional latencies within the scope of the present invention.

A further alternative embodiment shown in Figure 7 determines (740) that the port is a least-loaded port by determining (746) that the product of the net order count (710) for the port (216) multiplied by the latency (712) for the port (216) is not greater than the  
10 product of net order count (720, 730) and latency (722, 732) for any other port (218, 220) coupled to the market (222). In this illustrated embodiment, the latencies (712, 722, 732) and the net order counts (710, 720, 730) are stored in port data structures (702, 704, 706), one data structure for each port.

Turning to Figure 8, an overview of a further aspect of the invention is seen. Figure 8 shows a load balancing system (802) for automated trading of securities in which data communications loads are balanced among data communications ports (816-832). The load balancing system (802) in one embodiment illustrated in Figure 8 is coupled to a multiplicity of ports (816-832) organized so that one market is coupled to the broker-dealer system through more than one port, the markets identified in Figure 8 by reference  
20 numbers 834-838. In the embodiment illustrated, the load balancing system (832) is programmed to operate when a new order (814) from a broker-dealer system (810) is available and ready to be sent through a port (816-832) to a market (834-838). The load balancing system of the kind illustrated in Figure 8 is programmed to operate continually  
25 in turn upon each of the ports assigned to a market.

Turning now to Figure 9, more specific embodiments of a load balancing system (902) are shown. In one of the embodiments shown in Figure 9, the load balancing system (902) includes at least one computer processor (904) coupled (972) for data

communications to at least one broker-dealer system (908). In this embodiment, the processor is coupled (962-970) through data communications ports (932-940) to a market (950). In the illustration of Figure 9, only one market and one group of associated ports are shown. In most embodiments, the processor is coupled to more than one market, and each market is coupled to at least one port, as shown on Figure 8.

In a further embodiment shown in Figure 9, the processor (904) is programmed to receive (920) through a port (936) from a market (950) to which the port is coupled (956) a new acknowledgment (916) of an order previously sent through the port (974, 910) from the broker-dealer system to the market. In this illustrated embodiment, the processor is programmed to send (922) the new acknowledgment (916) to the broker-dealer system (908). This embodiment includes the processor programmed to determine (930) that the port (936) is not overloaded. In the illustrated embodiment, the determination that the port is not overloaded is dependent upon the previously-sent order (910), the new acknowledgment (916), and optionally also dependent upon other previous orders (912) and upon previous acknowledgments (918).

The embodiment illustrated in Figure 9 also includes the processor programmed to send (928) a new order (914) through the port (936) to the market (950). The processor's sending (928) the new order (914) is dependent upon the determination (930) that the port is not overloaded. More specifically, in embodiments of the kind illustrated, orders are sent to markets over through non-overloaded ports.

The embodiment illustrated in Figure 9 includes computer memory (906) coupled (976) to the processor (904). In the illustrated embodiment, the processor (904) is further programmed to store (924) in the computer memory (906) the new acknowledgment (916) and the new order (914).

In a further embodiment shown in Figure 10, the processor (904) programmed to

determine that a port is not overloaded (930) further comprises the processor programmed to determine (1002) that a latency (1020, 1022) for a port (932) is less than a maximum allowed latency (1024) for the port. Latency comprises a measure of the speed with which markets return acknowledgments for orders. In one embodiment  
5 shown in Figure 10, the latency for the port is an instant latency (1020). In an alternative embodiment, the latency for the port is an average latency (1024).

In embodiments using latencies as shown in Figure 10, the port latencies are dependent upon order data (1010) and acknowledgment data (1014) in that the latencies comprise  
10 various kinds of comparisons between order times (1012) and acknowledgment times (1016). Order times are the times when particular order were sent to a market, and acknowledgment times (1016) are the times when acknowledgments corresponding to particular orders were received back from markets.

More specifically, an instant latency (1020) is the difference between the time when a recent acknowledgment was received and the time when the acknowledgment's corresponding order was sent. In addition, as shown in Figure 5, an average latency in some embodiments is a decaying average (524) and in other embodiments is a moving average (522). Examples of methods and systems useful with the present invention for  
15 calculating latencies are set forth in Appendix I. The use of any method of programming a processor to calculate latency is well within the present invention.  
20

In the embodiment shown in Figure 10, the latency calculations (1018) are performed in a broker-dealer system (908) and provided (1026, 1028) to the load balancing system for  
25 storage in computer memory (906). In other embodiments, the processor in the load balancing system is programmed to calculate latencies. In the illustrated embodiment of Figure 10, the latencies are stored in memory in port data structures (1004-1008) with one data structure provided for each port (932-936) used with the system. An example of a useful port data structure is shown in Figure 5. Many alternative structures for port data

are useful within the scope of the invention.

A further embodiment of the invention as shown in Figure 11 includes the processor (906) programmed to decrement (1102) a net order count (504) for the port (932). The net order count (504) indicates the net number of orders sent through the port (932) to the market (950) for which acknowledgments have not yet been received from the market. In this embodiment, the net order count (504) is decremented (1102) after (1101) receiving (920) a new acknowledgment (916).

The embodiment shown in Figure 11 includes the processor (906) programmed to determine (1104) that the net order count (504) is less than a maximum allowed net order count (506) for the port (932). The maximum allowed net order count (506) indicates the maximum number of orders without acknowledgments allowed to be sent through the port (932). The fact that the net order count is less than the maximum allowed net order count for the port indicates that the port is not overloaded.

This embodiment illustrated in Figure 11 includes the processor programmed to increment (1106) the net order count. In some embodiments, the processor is programmed to increment (1106) the net order count after determining (1104) that the net order count is less than the maximum net order count but before (1108) sending a new order to market. In other embodiments, the processor is programmed to increment (1106) the net order count after determining (1104) that the net order count is less than the maximum net order count and after (1110) sending a new order to market.

A further embodiment of the invention shown in Figure 12 includes the processor (906) programmed to increment (1202) an acknowledgment count (510) for the port (932). The acknowledgment count (510) represents the number of acknowledgments received through the port during a defined period of time. An example of a period of time useful in the invention is one trading day. Various embodiments of the inventions use other

periods of time, shorter or longer. Any functional period of time is well within the scope of the invention.

5 A further embodiment of the invention shown on Figure 12 includes the processor (906) programmed to determine (1206) that an order count (508) for the port (932) exceeds the acknowledgment count (510) for the port (932) by at least a maximum allowed net order count (506). The order count (508) represents the number of orders sent through the port (932) during the defined period of time. The maximum net order count (506) indicates the maximum number of orders without acknowledgments allowed to be sent through the  
10 port (932). In this embodiment, the fact that the order count (508) for the port exceeds the acknowledgment count (510) for the port (932) by at least a maximum allowed net order count (506) indicates that the port is not overloaded.

The embodiment shown in Figure 12 includes also the processor programmed to  
15 increment (1204) the order count (508) for the port (932). In some embodiments, the processor is programmed to increment (1204) the order count (508) for the port (932) after determining (1206) that the order count (508) for the port (932) exceeds the acknowledgment count (510) for the port (932) by at least a maximum allowed net order count (506) but before (1208) sending (928) a new order to market. In other  
20 embodiments, the processor is programmed to increment (1204) the order count (508) for the port (932) after determining (1206) that an order count (508) for the port (932) exceeds the acknowledgment count (510) for the port (932) by at least a maximum allowed net order count (506) and after (1210) sending (928) a new order (914) through the port (932) to market (950).

25

A further embodiment shown on Figure 13 includes the processor (904) programmed to determine (1340), before sending (928) the new order through the port (932) to the market (950), that the port (932) is a least-loaded port. In this embodiment, the processor's sending (928) the order through the port to the market is dependent upon the

determination (1340) that the port is a least-loaded port. More specifically, in this kind of embodiment, orders are sent to markets only through least-loaded ports.

5 A further embodiment of the invention illustrated in Figure 13 includes a data structure (1302) for the port (932) having a net order count (1310) for the port (932). The net order count (1310) indicates the net number of orders sent through the port (932) to the market (950) for which acknowledgments have not yet been received from the market. In the illustrated embodiment, other ports (936, 940) coupled to the market (950) have data structures (1304, 1306) having net order counts (1320, 1330). In the illustrated  
10 embodiment, the processor (904) programmed to determine (1340) that the port is a least-loaded port further comprises the processor programmed to determine (1342) that the net order count (1310) for the port is not greater than any of the net order counts (1320, 1330) for the other ports coupled to the market (950).

15 A further embodiment of the invention illustrated in Figure 13 includes a port data structure (1302) in which the port data structure has a latency (1312) for the port (932). Latency comprises a measure of the speed with which markets return acknowledgments for orders. In this embodiment, other ports (936, 940) coupled to the market (950) have data structures (1304, 1306) having latencies (1322, 1332). In the illustrated  
20 embodiment, the processor (904) programmed to determine (1340) that the port is a least-loaded port comprises the processor (904) programmed to determine (1344) that the latency (1312) for the port (932) is not greater than any of the latencies (1322, 1332) for the other ports (1304, 1306) coupled to the market (950).

25 A further embodiment of the invention illustrated in Figure 13 includes a port data structure (1302) having a net order count (1310) for the port (932) and a latency (1312) for the port (932). The net order count (1310) indicates the net number of orders sent through the port (932) to the market (950) for which acknowledgments have not yet been received from the market. Latency comprises a measure of the speed with which markets

## CLAIMS

What is claimed is:

- 1 1. A method of balancing data communications loads among data communications ports  
2 in systems for automated trading of securities, the systems including at least one  
3 broker-dealer system coupled through at least one data communications system to  
4 more than one market system, the data communications system including a  
5 multiplicity of ports organized so that one market is coupled to the broker-dealer  
6 system through more than one port, the method operating as an adjunct to a broker-  
7 dealer system, the method applied when a new order from the broker-dealer system is  
8 available and ready to be sent through a port to a market; the method being applied  
9 continually in turn to each of the ports assigned to a market, the method comprising  
10 the steps of:  
11  
12 receiving through a port from a market to which the port is coupled a new  
13 acknowledgment of an order previously sent through the port from the  
14 broker-dealer system to the market;  
15 sending the new acknowledgment to the broker-dealer system;  
16 determining that the port is not overloaded, the determination being dependent  
17 upon the previously-sent order, the new acknowledgment, and optionally  
18 also dependent upon other previous orders and upon previous  
19 acknowledgments; and  
20 sending a new order through the port to the market, the sending of the new order  
21 being dependent upon the determination that the port is not overloaded.
- 1 2. The method of claim 1 wherein determining that the port is not overloaded comprises  
2 determining that a latency for the port is less than a maximum allowed latency for the  
3 port, wherein latency comprises a measure of the speed with which markets return

4 acknowledgments for orders.

1 3. The method of claim 1 further comprising decrementing a net order count for the  
2 port, wherein the net order count indicates the net number of orders sent through the  
3 port to the market for which acknowledgments have not yet been received from the  
4 market, wherein the net order count is decremented after receiving a new  
5 acknowledgment.

1 4. The method of claim 3 further comprising the steps of:

2  
3 determining that the net order count is less than a maximum allowed net order  
4 count for the port, wherein the maximum allowed net order count indicates the  
5 maximum number of orders without acknowledgments allowed to be sent  
6 through the port, wherein the net order count less than the maximum allowed  
7 net order count for the port indicates that the port is not overloaded; and  
8  
9 incrementing the net order count.

1 5. The method of claim 1 further comprising incrementing an acknowledgment count  
2 for the port, wherein the acknowledgment count represents the number of  
3 acknowledgments received through the port during a defined period of time.

1 6. The method of claim 5 further comprising the steps of:

2  
3 determining that an order count for the port exceeds the acknowledgment count  
4 for the port by at least a maximum allowed net order count, wherein the order  
5 count represents the number of orders sent through the port during the defined  
6 period of time, wherein the maximum allowed net order count indicates the  
7 maximum number of orders without acknowledgments allowed to be sent

8 through the port, wherein the order count for the port exceeding the  
9 acknowledgment count for the port by at least a maximum allowed net order  
10 count indicates that the port is not overloaded; and  
11  
12 incrementing the order count for the port.

1 7. The method of claim 1 further comprising determining, before sending the new order  
2 through the port to the market, that the port is a least-loaded port, wherein sending the  
3 order through the port to the market is dependent upon determining that the port is a  
4 least-loaded port.

1 8. The method of claim 7 wherein the port comprises a net order count, wherein the net  
2 order count indicates the net number of orders sent through the port to the market for  
3 which acknowledgments have not yet been received from the market, and other ports  
4 coupled to the market have net order counts, wherein determining that the port is a  
5 least-loaded port comprises determining that the net order count for the port is not  
6 greater than any of the net order counts for the other ports coupled to the market.

1 9. The method of claim 7 wherein the port comprises latency, wherein latency  
2 comprises a measure of the speed with which markets return acknowledgments for  
3 orders, wherein the other ports coupled to the market have latencies, wherein  
4 determining that the port is a least-loaded port comprises determining that the latency  
5 for the port is not greater than any of the latencies for the other ports coupled to the  
6 market.

1 10. The method of claim 7 wherein the port comprises a net order count and a latency,  
2 wherein the net order count indicates the net number of orders sent through the port to  
3 the market for which acknowledgments have not yet been received from the market,  
4 wherein latency comprises a measure of the speed with which markets return

acknowledgments for orders, wherein the other ports coupled to the market have net order counts and latencies, wherein determining that the port is a least-loaded port comprises determining that the product of the net order count for the port multiplied by the latency for the port is not greater than the product of net order count and latency for any other port coupled to the market.

11. A load balancing system for automated trading of securities in which data communications loads are balanced among data communications ports, the load balancing system coupled to a multiplicity of ports organized so that one market is coupled to the broker-dealer system through more than one port, the load balancing system operative when a new order from a broker-dealer system is available and ready to be sent through a port to a market, the load balancing system operative continually in turn upon each of the ports assigned to a market, the load balancing system comprising:

at least one computer processor coupled for data communications to at least one broker-dealer system and coupled through data communications ports to more than one market, the processor programmed to:

receive through a port from a market to which the port is coupled a new acknowledgment of an order previously sent through the port from the broker-dealer system to the market;  
send the new acknowledgment to the broker-dealer system;  
determine that the port is not overloaded, the determination being dependent upon the previously-sent order, the new acknowledgment, and optionally also dependent upon other previous orders and upon previous acknowledgments; and  
send a new order through the port to the market, the sending of the new order being dependent upon the determination that the port is not overloaded; and

24 computer memory coupled to the processor, the processor further  
25 programmed to store in the computer memory the new  
26 acknowledgment and the new order.

1 12. The load balancing system of claim 11 wherein the processor programmed to  
2 determine that the port is not overloaded comprises the processor programmed to  
3 determine that a latency for the port is less than a maximum allowed latency for the  
4 port, wherein latency comprises a measure of the speed with which markets return  
5 acknowledgments for orders.

1 13. The load balancing system of claim 11 further comprising the processor programmed  
2 to decrement a net order count for the port, wherein the net order count indicates the  
3 net number of orders sent through the port to the market for which acknowledgments  
4 have not yet been received from the market, wherein the net order count is  
5 decremented after receiving a new acknowledgment.

1 14. The load balancing system of claim 13 further comprising the processor programmed  
2 to:  
3

4 determine that the net order count is less than a maximum allowed net order count  
5 for the port, wherein the maximum allowed net order count indicates the  
6 maximum number of orders without acknowledgments allowed to be sent  
7 through the port, wherein the net order count less than the maximum allowed  
8 net order count for the port indicates that the port is not overloaded; and  
9

10 increment the net order count.

1 15. The load balancing system of claim 11 further comprising the processor programmed  
2 to increment an acknowledgment count for the port, wherein the acknowledgment

3 count represents the number of acknowledgments received through the port during a  
4 defined period of time.

1 16. The load balancing system of claim 15 further comprising the processor programmed  
2 to:

3  
4 determine that an order count for the port exceeds the acknowledgment count for  
5 the port by at least a maximum allowed net order count, wherein the order  
6 count represents the number of orders sent through the port during the defined  
7 period of time, wherein the maximum allowed net order count indicates the  
8 maximum number of orders without acknowledgments allowed to be sent  
9 through the port, wherein the order count for the port exceeding the  
10 acknowledgment count for the port by at least a maximum allowed net order  
11 count indicates that the port is not overloaded; and

12  
13 increment the order count for the port.

1 17. The load balancing system of claim 11 further comprising the processor programmed  
2 to determine, before sending the new order through the port to the market, that the  
3 port is a least-loaded port, wherein sending the order through the port to the market is  
4 dependent upon the determination that the port is a least-loaded port.

1 18. The load balancing system of claim 17 wherein a data structure for the port comprises  
2 a net order count for the port, wherein the net order count indicates the net number of  
3 orders sent through the port to the market for which acknowledgments have not yet  
4 been received from the market, and other ports coupled to the market have data  
5 structures having net order counts, wherein the processor programmed to determine  
6 that the port is a least-loaded port comprises the processor programmed to determine  
7 that the net order count for the port is not greater than any of the net order counts for

8 the other ports coupled to the market.

1 19. The load balancing system of claim 17 wherein a data structure for the port comprises  
2 latency, wherein latency comprises a measure of the speed with which markets return  
3 acknowledgments for orders, wherein the other ports coupled to the market have data  
4 structures having latencies, wherein the processor programmed to determine that the  
5 port is a least-loaded port comprises the processor programmed to determine that the  
6 latency for the port is not greater than any of the latencies for the other ports coupled  
7 to the market.

1 20. The load balancing system of claim 17 wherein a data structure for the port comprises  
2 a net order count and a latency, wherein the net order count indicates the net number  
3 of orders sent through the port to the market for which acknowledgments have not yet  
4 been received from the market, wherein latency comprises a measure of the speed  
5 with which markets return acknowledgments for orders, wherein the other ports  
6 coupled to the market have data structures having net order counts and latencies,  
7 wherein the processor programmed to determine that the port is a least-loaded port  
8 comprises the processor programmed to determine that the product of the net order  
9 count for the port multiplied by the latency for the port is not greater than the product  
10 of net order count and latency for any other port coupled to the market.

[illegible]

communications ports in systems for automated trading of securities. Embodiments

typically include receiving acknowledgments of orders previously sent through a port from a broker-dealer system to a market, sending acknowledgments to the broker-dealer system, and determining that port are not overloaded. Various embodiments make determinations of overload on the basis of latency, net order count, or order count compared with acknowledgment count. Alternative embodiments send orders only through least-loaded ports. Least-loaded ports are identified on the basis of latency, net order count, or a combination of the two.

## APPENDIX I

5 *Specification And Figures to:* U.S. Patent Application Serial No. 09/574,595 entitled  
“Latency Monitor,” inventor Michael Bundy, Attorney Docket Number 30418US, filed  
May 19, 2000, 21 pages of Specification and Figure 1A through Figure 9, attached hereto  
and *incorporated herein by reference.*

## BACKGROUND

10 Broker-dealers increasingly make available to their customers on-line submission,  
cancellation, and tracking of the status of orders for securities. Securities trading  
customers include day traders, institutions, and active private investors. Such customers  
15 make many quick decisions regarding when and from whom to order securities.  
Customers are increasingly demanding regarding quality and speed of execution.  
Customers require a high quality of information to support their decision-making.  
Customers are often presented with quotes identifying markets from which particular  
securities can be bought or sold at particular prices. In such quotes there are often several  
20 markets quoting securities at the current inside price. Markets quoting the same price,  
however, are not the same in terms of quality of execution. Especially regarding speed,  
all markets are different. It would be useful, therefore, if customers had a display of  
information helpful in identifying which markets are likely to execute orders more  
quickly than others.

25 Modern broker-dealers often subscribe to one or more exchanges or ECNs (“markets”)  
capable of executing orders for securities by matching orders with orders of opposite  
side. Orders, cancellations, and responses are communicated to and from markets by use  
of data communications ports. Many broker-dealers handle volumes of orders so large  
30 as to require more than one port per market. Ports often are not equal in their ability to  
communicate with a particular market. Sometimes ports fail, partially or completely. It  
would be useful to have a display of information, for diagnostic purposes within the  
broker-dealer organizations, to help identify problems with particular ports, to help keep  
the overall flow of data communications functioning efficiently.

## SUMMARY

One aspect of the invention provides methods for displaying latency. Embodiments of the invention are typically implemented in broker-dealer computer systems engaged generally in automated processing of orders for securities including sending to markets messages comprising orders and cancellations and receiving from markets responses to orders and cancellations. Embodiments include recording for messages sent to markets the time when each message is sent and the identity of the market to which each message is sent. Embodiments include recording for responses received from markets the time when each response is received, wherein each response corresponds to a particular message. Embodiments include calculating latencies for markets dependent upon recorded time when a message is sent to the market and a recorded time when a corresponding response is received from the market. Embodiments include latencies for ports as well as latencies for markets. Embodiments include displaying the identity of the markets and the latencies for the markets. Embodiments include counting and displaying the number of messages and responses received and sent during a period of time, for use in broker-dealer diagnostics.

A second aspect of the invention provides automated computing machinery, as system for calculating and displaying latency, typically implemented in broker-dealer computer systems capable of automated processing of orders for securities, includes sending messages to markets and receiving from markets responses to messages. Embodiments of this aspect include at least one computer processor programmed to record in computer memory, for messages sent to markets, the time when each message is sent and the identity of the market to which each message is sent. In such embodiments, processors are typically programmed also to record in computer memory, for responses received from markets, the time when each response is received. Each response corresponds to a particular message. In such embodiments, processors are programmed also to calculate for markets latencies dependent upon recorded time when at least one message is sent to a market and recorded time when a corresponding response is received from the market. In such embodiments, processors typically are programmed also to display the identities

of the markets and the latencies for the markets. Embodiments include latencies for ports as well as latencies for markets. Embodiments of this aspect typically include computer memory coupled to processors, the processors being further programmed to store in computer memory the latencies. Embodiments include processors programmed to count and display the number of messages and responses received and sent during a period of time, for use in broker-dealer diagnostics.

## DETAILED DESCRIPTION OF EXEMPLARY EMBODIMENTS

Definitions:

“Cancellation” is termination of an order, or partial termination of an order, by the

customer or by software comprising an embodiment of the invention. In addition, markets can cancel orders, or parts of orders, for example, in response to an IOC order.

“ECN” abbreviates “Electronic Communications Network,” referring to an order matching service that provides liquidity by matching orders rather than by maintaining inventory. In the context of the invention, ECNs are considered markets. ECNs, like market makers are identified by use of market participant identification codes or “MPIDs.” In order to avoid confusion with data communications networks, ECNs are referred to as either “ECNs” or as “markets.” Some current ECNs, their symbols and names, are listed below. The number and identities of ECNs changes from time to time.

<u>Example List of ECNs</u>	
<u>MPID</u>	<u>Name</u>
ARCA	Archipelago
BTRD	Bloomberg Trade Book
INCA	Instinet
ISLD	Island
MWSE	Midwest Stock Exchange
NTRD	NexTrade
REDI	Speer Leeds

“Exchange” means a national, regional, or international exchange for securities trading including for example, Nasdaq or NYSE.

“Executed,” in reference to an order, means that shares have been either bought or sold according to the side of the order.

“Filled” means executed. That is, all shares in the order have been executed, bought or sold according to the side of the order. If an order is subject to partial fulfillment, then the order can be partly filled and partly rejected or cancelled, in which case the order will never be considered filled. Processing of an order can therefore be completed through

some combination of cancellation, rejection, killing, and partial execution without the order's ever being filled. Processing of an order is said to be complete when all the shares in the order, share by share, have been executed, cancelled, rejected, or killed.

- 5 "Inside price" means, as appropriate, the highest bid price or the lowest ask price for a particular security. For buy orders, the inside price is the lowest ask price. For sell orders, the inside price is the highest bid price.

- 10 "Latency" means a measure of the speed with which markets respond to orders and cancellations. Latency in many embodiments of the invention is determined as the difference between the time when a response to an order is received and the time when the corresponding order was routed to the market. Latency can be measured from normal orders or from test orders. Some markets support test orders as such. For markets in which test orders as such are not supported, test orders can be implemented by use of  
15 unmarketable orders immediately followed by cancellations. For markets receiving orders regularly, latency can be tracked from normal orders, without the need for test orders. Latency can be embodied as a single ratio difference between two recorded times or as various kinds of averages.

- 20 "Level Two Quotes" are quotes that comprise one or more market participant quotes ("MPQs"). The best known source of level two quotes is Nasdaq, but "level two quotes" refers to any form of market information that aggregates market participant quotes for a security.

- 25 "Market," "electronic market," "market participant," "electronic market participant," "marketing network," and electronic marketing network" are all used as synonyms for services accessible through electronic communications networks capable of executing orders for securities by accepting from broker-dealers buy orders and sell orders, matching or failing to match buy orders with sell orders, and communicating the results  
30 to the broker-dealers. Generally the term "market" is used to refer to these entities. All "markets," as the term is used, are either ECNs or market makers. All available markets

have names and symbols as described under the definitions of “ECN” and “market maker.”

- 5 “Market maker” means a broker-dealer providing order matching and liquidity in a stock by maintaining an inventory of the stock. Market makers typically trade their inventories through exchanges. Some currently active market makers, their symbols and names, are listed below. The number and identity of market makers can change from time to time.

<b>Example List of Market Makers</b>	
<b><u>MPID</u></b>	<b><u>Name</u></b>
BEST	Bear, Stearns & Co., Inc.
BTAB	Alex, Brown & Sons, Inc.
GSCO	Goldman, Sachs & Co.
HMQT	Hambrecht & Quist, LLC
HRZG	Herzog, Heine, Geduld, Inc.
JANY	Janney Montgomery Scott, Inc.
LEHM	Lehman Brothers, Inc.
MADF	Bernard L. Madoff
MLCO	Merrill Lynch, Pierce, Fenner & Smith Inc.
MOKE	Morgan, Keehan & Co., Inc.
MONT	Nationsbanc Montgomery Securities, LLC
MSCO	Morgan Stanley & Co., Inc.
NITE	Knight Securities, L.P.
OLDE	Olde Discount Corporation
OPCO	CIBC Oppenheimer Corporation
PIPR	Piper Jaffray Inc.
PRUS	Prudential Securities, Inc.
PWJC	Paine Webber, Inc.

RAJA	Raymond James & Associates, Inc.
SBSH	Smith Barney, Inc.
SHRP	Sharpe Capital, Inc.
SHWD	Sherwood Securities Corporation

“Orders” are orders for purchase or sale of securities. In many of the embodiments described, “orders” are electronic orders for purchase or sale of securities.

5 “Quotes” are aggregates of information regarding securities traded in markets. Quotes include for securities listed for sale or purchase, symbols identifying the securities, price, side, quantities, and market identifications or MPIDs. Quotes can come from exchanges or directly from markets. A “Nasdaq Level Two Quote” includes market information in the form of market participant quotes for all markets offering to buy or sell a particular  
10 security through Nasdaq.

“Securities” are any agreement for investment. Stocks are the securities most often addressed in described embodiments of the invention. The invention, however, is applicable to many kinds of securities including, for example, options, commodities, and  
15 bonds.

“Side” refers to which side of the market is represented by an order or a quote. Side indicates whether the quote or order is to buy or sell, bid or ask. “Bid” indicates the buy side. “Ask” indicates the sell side. The present invention functions equally for either  
20 side of a transaction. Therefore we attempt to speak in neutral terms regarding side. We speak of execution rather than buying or selling. We use the term “price improvement” to indicate both price reductions for buy orders and price increases for sell orders.

Detailed Description:

25 Turning now to Figure 1A, a first aspect of the invention is seen. One embodiment illustrated in Figure 1A provides a method of displaying latency. The embodiment is

implemented in a broker-dealer computer system. The system is engaged in automated processing of orders (150) for securities including sending (104) messages (102) to markets (108) and receiving (112) from markets (108) responses (114) to messages.

- 5 The illustrated embodiment includes recording (106) for messages sent to markets the time (120) when each message is sent and the identity (118) of the market to which each message is sent, the messages (102) comprising orders (150) and cancellations (148) of orders. This first embodiment includes also recording (110) for responses received from markets the time (122) when each response is received, wherein each response  
10 corresponds to a particular message.

- This embodiment includes also calculating (124) for at least one market a latency (128) dependent upon at least one recorded time (120) when at least one message is sent to the market and at least one recorded time (122) when a corresponding response is received  
15 from the market. The illustrated embodiment includes displaying (130) the identity (118) of the market and the latency (128) for the market. In a further embodiment shown in Figure 1A, latency (128) is a latency for a port (154), the port being identified by Port ID code (156).

- 20 Shown in Figure 5A is an example of a form of display useful with many embodiments of the invention. The example in Figure 5A illustrates a columnar display of identities (118) of markets and latency implemented as an instant latency (502) for each market and an average latency (504) for each market.

- 25 As shown on Figure 1A, the display function (130) in many embodiments sends (133) the display (135) to display devices (134) by use of data communications (132). Data communications (132) in some embodiments includes networks, such as intranets, extranets, or internets, and in other embodiments includes satellite channels, direct telephone links, and other forms of data communications. Use of any form of data

communications is well within the invention.

In a further embodiment, shown in Figure 2, latency is implemented as an instant latency (202). The instant latency (202) is calculated (204) dependent upon one recorded time (120) when one message is sent to a market and one recorded time (122) when a  
5 corresponding response is received from the market.

In a still further embodiment, shown in Figure 3, latency is implemented as an average latency (320). The average latency (320) is dependent upon at least one recorded time (306, 314) when at least one message is sent to the market and at least one recorded time  
10 (308, 316) when a corresponding response is received from the market. In embodiments of the kind shown in Figure 3, the recorded times (306, 308, 314, 316) used in calculating the average latency (320) are recorded during a defined period of time (322).

15 In a further embodiment, shown in Figure 4, the latency is implemented as an average latency (420). The average latency is dependent upon at least one recorded time (408, 414) when at least one message is sent to the market and at least one recorded time (410, 416) when a corresponding response is received from the market. In embodiments shown in Figure 4, the number of recorded times (408, 410, 414, 416) used to calculate the  
20 average latency (420) is limited to a defined maximum number "N" (422). In many embodiments of this kind, the N recorded times used to calculate average latency are the N most recent recorded times.

A further embodiment shown in Figure 1A includes the steps of counting (136) the  
25 number of messages sent to at least one market during a period of time, including storing in computer memory (140) the number of messages (144) sent to the market during the period of time. In many embodiments of this kind, the counting steps (138, 136) determine time periods in dependence upon a computer system clock (170).

30 The illustrated embodiment includes also counting (138) the number of responses

received from the market during the period of time, including storing in computer memory (140) the number of responses (146) received from the market during the period of time. The embodiment includes also displaying (130), in addition to the identity (118) of the market and the latency (128) for the market, the number of messages (144) sent to the market and the number of responses (146) received from the market during the period of time.

Figure 5C shows an example of a display useful with various embodiments using such displays display in columnar form the market identities (118), latencies (320), number of messages sent during a period of time (144), and the number of responses received during a period of time (146). As shown on Figure 1A, the display function (130) in many embodiments sends (133) the display (135) to display devices (134) by use of data communications (132). Data communications (132) in some embodiments includes networks, such as intranets, extranets, or internets, and in other embodiments includes satellite channels, direct telephone links, and other forms of data communications. Use of any form of data communications is well within the invention.

An example of the use of message counts for diagnostic purposes is a display showing an increase in latency for a port explained by an increase in message counts for the port, thus indicating the port slowed down because its work load increased, and indicating also that there is no problem with the system. Another example is a display showing an increase in latency for a port explained by the port's message count going to zero, thus indicating that the increase in latency is caused by a catastrophic failure of the port.

In a further embodiment, shown in Figure 1A, the system includes the steps of counting (136) the number of messages sent to a market through a port (154) during a period of time, including storing in computer memory (140) the number of messages (144) sent to the market through the port during the period of time. In many embodiments of this kind, the counting steps (138, 136) determine time periods in dependence upon a computer system clock (170).

The illustrated embodiment includes also counting (138) the number of responses received from the market through the port during the period of time, including storing in computer memory (140) the number of responses (146) received from the market through the port during the period of time. The system includes also displaying (130), in addition to the identity (118) of the market and the latency (128) for the market, the number of messages (144) sent to the market through the port and the number of responses (146) received from the market through the port during the period of time.

Figure 5B shows an example of a display useful with various embodiments of the invention. Embodiments using such displays display in columnar form the market identities (118), port identity codes (154), instant latencies (202), average latencies (320), number of messages sent during a period of time (144), and the number of responses received during a period of time (146).

As shown on Figure 1A, the display function (130) in many embodiments sends (133) the display (135) to display devices (134) by use of data communications (132). Data communications (132) in some embodiments includes networks, such as intranets, extranets, or internets, and in other embodiments includes satellite channels, direct telephone links, and other forms of data communications. Use of any form of data communications is well within the invention.

Turning now to Figure 6, an additional aspect of the invention is seen. One embodiment shown in Figure 6 is automated computing machinery implementing a broker-dealer computer system (602). The illustrated embodiment is capable of automated processing of orders for securities, including sending (606) messages (604) to markets (608) and receiving (610) from markets (608) responses (612) to messages.

The illustrated embodiment includes at least one computer processor (618) programmed to record (622) in computer memory (620), for messages sent to markets, the time (632)

when each message is sent and the identity (630) of the market (608) to which each message is sent, the messages including orders (614) and cancellations (616) of orders. In this embodiment, the processor is programmed also to record (624), in computer memory (620), for responses (612) received (610) from markets, the time (634) when each response is received. Each response (612) corresponds (642) to a particular message (604).

In this example embodiment, the processor is programmed also to calculate (626), for at least one market (608) a latency (628) dependent upon at least one recorded time (632) when at least one message is sent to the market and at least one recorded time (634) when a corresponding response is received from the market. In this embodiment, the processor is programmed also to display (632) of the identity (630) of the market and the latency (628) for the market. In a further embodiment shown in Figure 6, latency (628) for a market (608) is also latency for a port (644), the port being identified in data by a port ID code (646).

As shown on Figure 6, the display function (632) in many embodiments sends (633) the display (635) to display devices (638) by use of data communications (636). Data communications (636) in some embodiments includes networks, such as intranets, extranets, or internets, and in other embodiments includes satellite channels, direct telephone links, and other forms of data communications. Use of any form of data communications is well within the invention. The embodiment illustrated in Figure 6 includes also computer memory (620) coupled (640) to the processor (618), the processor being further programmed to store (630) in computer memory (620) the latency (628).

In a further embodiment shown in Figure 7, latency comprises an instant latency. In the embodiment of Figure 7, the processor (618) is programmed to calculate (626) latency as an instant latency (702) calculated dependent upon one recorded time (632) when one message is sent to a market and one recorded time (634) when a corresponding response is received from the market.

In some embodiments, the processor is programmed to calculate latency as an average latency dependent upon at least one recorded time when at least one message is sent to the market and at least one recorded time when a corresponding response is received from the market. In such embodiments, as illustrated in Figure 3, recorded times (306,  
5 308, 314, 316) used in calculating the average latency (320) are recorded during a defined period of time (322).

In other embodiments, the processor is programmed to calculate latency as an average latency dependent upon at least one recorded time when at least one message is sent to  
10 the market and at least one recorded time when a corresponding response is received from the market. In such embodiments, as shown in Figure 4, the number of the recorded times (408, 410, 414, 416) used to calculate the average latency is limited to a defined maximum number "N" (422). In many embodiments of this kind, the N recorded times used to calculate average latency are the N most recent recorded times.

15 In a further embodiment shown in Figure 8, latency comprises an average latency. In embodiments of the kind shown in Figure 8, the processor (618) is further programmed to count (802) the number (806) of messages (604) sent (606) to at least one market (608) during a period of time, including storing in computer memory (620) the number of  
20 messages (806) sent to the market during the period of time. Periods of time in many embodiments are determined dependent upon a system clock (816).

The processor in many embodiments of the kind illustrated in Figure 8, is also programmed to count (804) the number (808) of responses (612) received (610) from the  
25 market (608) during the period of time, including storing in computer memory (620) the number of responses (808) received from the market during the period of time. The system includes also displaying (814), in addition to the identity of the market and the

latency for the market, the number of messages (806) sent to the market and the number of responses (808) received from the market during the period of time.

Figure 5C shows an example of a display useful with various embodiments of the invention. Embodiments using such displays display in columnar form the market identities (118), latencies (320), number of messages sent during a period of time (144), and the number of responses received during a period of time (146). As shown on Figure 8, the display function (814) in many embodiments sends (815) the display (817) to display devices (638) by use of data communications (636). Data communications (636) in some embodiments includes networks, such as intranets, extranets, or internets, and in other embodiments includes satellite channels, direct telephone links, and other forms of data communications. Use of any form of data communications is well within the invention.

In a further embodiment shown in Figure 9, the processor (618) is programmed to count (904) the number of messages (604) sent to a market (608) through a port (902) during a period of time, including storing (914) in computer memory (620) the number of messages (912) sent to the market (608) through the port (902) during the period of time. Periods of time in such embodiments typically are determined dependent upon a system clock (816).

The processor in many embodiments of the kind illustrated in Figure 9 is also programmed to count (906) the number of responses (612) received (610) from the market (608) through the port (902) during the period of time, including storing (916) in computer memory (620) the number of responses (910) received from the market (608) through the port (902) during the period of time. The embodiment as illustrated includes

also displaying (908), in addition to the identity (630 on Figure 6) of the market and the latency (628 on Figure 6) of the market, the number of messages (912) sent to the market (608) through the port (902) and the number of responses (910) received from the market (608) through the port (902) during the period of time.

5

Figure 5B shows an example of a display useful with various embodiments of the invention. Embodiments using such displays display in columnar form the market identities (118), port identity codes (154), instant latencies (202), average latencies (320), number of messages sent during a period of time (144), and the number of responses  
10 received during a period of time (146). As shown on Figure 9, the display function (908) in many embodiments sends (909) the display (911) to display devices (638) by use of data communications (636). Data communications (636) in some embodiments includes networks, such as intranets, extranets, or internets, and in other embodiments includes satellite channels, direct telephone links, and other forms of data communications. Use  
15 of any form of data communications is well within the invention.

## CLAIMS

What is claimed is:

- 1 1. A method of displaying latency, the method implemented in a broker-dealer  
2 computer system, the system being engaged in automated processing of orders for  
3 securities including sending messages to markets and receiving from markets responses  
4 to messages, the method comprising the steps of:  
5 recording for messages sent to markets the time when each message is sent and the  
6 identity of the market to which each message is sent, the messages comprising orders  
7 and cancellations of orders;  
8 recording for responses received from markets the time when each response is received,  
9 wherein each response corresponds to a particular message;  
10 calculating for at least one market a latency dependent upon at least one recorded time  
11 when at least one message is sent to the market and at least one recorded time when a  
12 corresponding response is received from the market;  
13 displaying the identity of the market and the latency for the market.
- 1 2. The method of claim 1 wherein the latency for a market further comprises latency for  
2 a port.
- 1 3. The method of claim 1 wherein the latency comprises an instant latency calculated  
2 dependent upon one recorded time when one message is sent to a market and one  
3 recorded time when a corresponding response is received from the market.
- 1 4. The method of claim 1 wherein the latency comprises an average latency dependent  
2 upon at least one recorded time when at least one message is sent to the market and at  
3 least one recorded time when a corresponding response is received from the market,  
4 wherein all the recorded times used in calculating the latency are recorded during a  
5 defined period of time.

1 5. The method of claim 1 wherein the latency comprises an average latency dependent  
2 upon at least one recorded time when at least one message is sent to the market and at  
3 least one recorded time when a corresponding response is received from the market,  
4 wherein the number of recorded times used to calculated the average latency is limited to  
5 a defined maximum.

1 6. The method of claim 1 wherein the latency comprises an average latency dependent  
2 upon at least one recorded time when at least one message is sent to the market and at  
3 least one recorded time when a corresponding response is received from the market,  
4 wherein the calculating uses the latest recorded time when a message is sent to the market  
5 and the latest recorded time when a corresponding response is received from the market,  
6 and wherein the number of recorded times used to calculated the average latency is  
7 limited to a defined maximum.

1 7. The method of claim 1 further comprising the steps of:  
2 counting the number of messages sent to at least one market during a period of time,  
3 including storing in computer memory the number of messages sent to the market during  
4 the period of time;  
5 counting the number of responses received from the market during the period of  
6 time, including storing in computer memory the number of responses  
7 received from the market during the period of time; and  
8 displaying, in addition to the identity of the market and the latency for the market,  
9 the number of messages sent to the market and the number of responses  
10 received from the market during the period of time.

1 8. The method of claim 1 further comprising the steps of:  
2 counting the number of messages sent to a market through a port during a period  
3 of time, including storing in computer memory the number of messages  
4 sent to the market through the port during the period of time;  
5 counting the number of responses received from the market through the port

2 further comprises latency for a port.

1 11. The automated computing machinery of claim 9 wherein the processor is further  
2 programmed to calculate latency as an instant latency calculated dependent upon one

1 recorded time when one message is sent to a market and one recorded time when a  
2 corresponding response is received from the market.

1 12. The automated computing machinery of claim 9 wherein the processor is further  
2 programmed to calculate latency as an average latency dependent upon at least one  
3 recorded time when at least one message is sent to the market and at least one recorded  
4 time when a corresponding response is received from the market, wherein all the  
5 recorded times used in calculating the latency are recorded during a defined period of  
6 time.

1 13. The automated computing machinery of claim 9 wherein the processor is further  
2 programmed to calculate latency as an average latency dependent upon at least one  
3 recorded time when at least one message is sent to the market and at least one recorded  
4 time when a corresponding response is received from the market, wherein the number of  
5 recorded times used to calculate the average latency is limited to a defined maximum.

1 14. The automated computing machinery of claim 9 wherein the latency comprises an  
2 average latency dependent upon at least one recorded time when at least one message is  
3 sent to the market and at least one recorded time when a corresponding response is  
4 received from the market, wherein the processor is further programmed to calculate  
5 latency dependent upon the latest recorded time when a message is sent to the market and  
6 the latest recorded time when a corresponding response is received from the market, and  
7 wherein the processor is further programmed to use in calculating average latency a  
8 number of recorded times limited to a defined maximum.

1 15. The automated computing machinery of claim 9 further comprising the processor

2 further programmed to:

1 count the number of messages sent to at least one market during a period of time,  
2 including storing in computer memory the number of messages sent to the  
3 market during the period of time;  
4 count the number of responses received from the market during the period of  
5 time, including storing in computer memory the number of responses  
6 received from the market during the period of time; and  
7 display, in addition to the identity of the market and the latency for the market,  
8 the number of messages sent to the market and the number of responses  
9 received from the market during the period of time.

10

11 16. The automated computing machinery of claim 9 further comprising the processor  
12 further programmed to:

13 count the number of messages sent to a market through a port during a period of  
14 time, including storing in computer memory the number of messages sent  
15 to the market through the port during the period of time;  
16 count the number of responses received from the market through the port during  
17 the period of time, including storing in computer memory the number of  
18 responses received from the market through the port during the period of time;  
19 and  
20 display, in addition to the identity of the market and the latency for the market,  
21 the number of messages sent to the market through the port and the  
22 number of responses received from the market through the port during the  
23 period of time.

## ABSTRACT

Method and system for displaying latency, useful in broker-dealer computer systems engaged generally in automated processing of orders for securities including sending to  
5 markets messages comprising orders and cancellations and receiving from markets responses to orders and cancellations, including recording for messages sent to markets the time when each message is sent and the identity of the market to which each message is sent, including recording for responses received from markets the time when each response is received, wherein each response corresponds to a particular message.  
10 Embodiments include calculating latencies for markets dependent upon recorded time when a message is sent to the market and a recorded time when a corresponding response is received from the market. Latencies are embodied alternatively as instant values or various kinds of averages. Embodiments includes latencies for communications ports as well as for markets. Embodiments include counting messages and responses for markets  
15 and for ports, and displaying the counts. Embodiments include displaying the identity of the markets and the latencies for the markets.

## COMBINED DECLARATION AND POWER OF ATTORNEY

As a below named inventor, I hereby declare that:

My residence, post office address and citizenship are as stated below next to my name.

I believe I am an original inventor of the subject matter which is claimed and for which a patent is sought on the invention entitled

### APPARATUS AND METHOD FOR LOAD BALANCING AMONG DATA COMMUNICATIONS PORTS IN AUTOMATED SECURITIES TRADING SYSTEMS

the specification of which: (check one) ☒ is attached hereto.

☐ was filed on \_\_\_\_\_

Attorney Docket No. T30411US

I hereby state that I have reviewed and understand the contents of the above-identified specification, including the claims, as amended by any amendment referred to above.

I acknowledge the duty to disclose to the United States Patent and Trademark Office all information known by me which is material to the patentability of this application in accordance with Title 37, Code of Federal Regulations §1.56.

I hereby claim foreign priority benefits under Title 35, United States Code, § 119 of any foreign application(s) for patent or inventor's certificate having a filing date before that of the application on which priority is claimed: **NONE**

Prior Foreign Application(s):
